# Conclusion

- Problem: MDP planning problem with large state space
- Goal: find near-optimal policy in low dimensional family of policies
- Novel framework for linearly solvable MDPs
- Also: Algorithm with complexity that scales with dimension of family
- First theoretical bounds for approximate solutions in linearly solvable MDPs
- Demonstrate on pratical example

## Previous work

- Approximate Dynamic Programming (linear approximation of the value function): [Sutton and Barto, 1998, Bertsekas, 2007]
- Approximate Linear Programming: (approximately solving LP) [Schweitzer and Seidmann, 1985, de Farias and Van Roy, 2003, 2004, 2006, Hauskrecht and Kveton, 2003, Guestrin et al., 2004, Petrik and Zilberstein, 2009, Desai et al., 2012, Veatch, 2013].
- Solving LMDPs (with no theoretical guarantees): [Todorov, 2009] and [Zhong and Todorov, 2011a,b]
- Approximate policy iteration (e.g. least squares policy iteration)

Extending to large dimensions

★ ∃ > < ∃ >

## Large Scale MDPs

- Markov decision process: modeling sequential decisions
- E.g. queueing network, robot planning
- Can solve for small state spaces
- Applications have *large* state spaces

# Notation

A Markov Decision Process is specified by:

- State space  $\mathcal{X} = \{1, \dots, X\}$
- Action space A
- Transition Kernel  $K : \mathcal{X} \times \mathcal{A} \to \triangle_{\mathcal{X}}$
- Loss function  $\ell : \mathcal{X} \times \mathcal{A} \to \mathbb{R}^+$

Problem:

- Policy  $\pi: \mathcal{X} \to \triangle_{\mathcal{A}}$
- Find policy to minimize value function

$$\boldsymbol{J}_{\pi}(\boldsymbol{x}) = \mathbb{E}\left[\sum_{t=0}^{\infty} \ell(\boldsymbol{X}_t, \pi) \middle| \boldsymbol{X}_0 = \boldsymbol{x}\right]$$

Aim for optimality within a restricted family of policies.

• □ ▶ • @ ▶ • ■ ▶ • ■ ▶ ·

### Large state space

- Parametric class of value functions  $J_{\theta}$  for  $\theta \in \Theta \subset \mathbb{R}^d$
- Bellman operator:

$$(\boldsymbol{LJ})(\boldsymbol{x}) = \min_{\boldsymbol{a} \in \mathcal{A}} \left\{ \ell(\boldsymbol{x}, \boldsymbol{a}) + \mathbb{E}_{\boldsymbol{x}' \sim P_0(\boldsymbol{x}, \boldsymbol{a})} \boldsymbol{J}(\boldsymbol{x}') \right\}$$

- Optimal policy  $J^*$  is a fixed point:  $LJ^* = J^*$
- Greedy policy:  $\pi_{J_{\theta}}$  (the argmin)
- Ultimate goal: find a  $\theta$  to minimize

the actual value of the greedy policy of the approximate optimal value

 $J_{\pi_{J_o}},$ 

э

## Approximate solutions

#### Consider the unconstrained surrogate

$$\min_{\theta} \boldsymbol{c}^{\top} \boldsymbol{J}_{\theta} + \| \boldsymbol{L} \boldsymbol{J}_{\theta} - \boldsymbol{J}_{\theta} \|$$

#### • Can we solve this with algorithms that scale with *d* but not *X*?

A B F A B F

3 Extending to large dimensions

### **KL-cost**

- Introduced in [Todorov, 2006]
- $\mathcal{A} = \triangle_{\mathcal{X}}$
- Loss:  $\ell(\mathbf{x}, \mathbf{P}) = q(\mathbf{x}) + D_{KL}(\mathbf{P}||\mathbf{P}_0(\cdot|\mathbf{x}))$ 
  - state loss q(x), base dynamics P<sub>0</sub>
  - infinite loss unless  $P \ll P_0$
- Terminal state z
- Total cost of policy P

$$\boldsymbol{J}_{\boldsymbol{P}}(\boldsymbol{x}) = \mathbb{E}\left[\sum_{t=0}^{\infty} \ell(\boldsymbol{X}_t, \boldsymbol{P}) \middle| \boldsymbol{X}_0 = \boldsymbol{x}\right]$$

э

### Linearly Solvable

Greedy action is:

$$P_{J}(\cdot|\mathbf{x}) = \underset{P \in \Delta_{\mathbf{x}}}{\operatorname{arg\,min}} \mathbb{E}_{y \sim P(\cdot|\mathbf{x})}[q(y) + J_{P}(y)] \propto P_{0}(\cdot|\mathbf{x})e^{-J_{P}(\cdot)}$$

• Bellman's operator becomes linear in  $g(x) = e^{-J(x)}$ :

$$e^{-LJ(x)} = e^{-q(x)} \sum_{x'} P_0(x, x') e^{-J(x')}$$

Bellman's optimality equation:

$$LJ = J \Leftrightarrow e^{-q}P_0e^{-J} = e^{-J}$$

Abbasi-Yadkori, Bartlett, Chen, Malek

э

## Parameterizing $\boldsymbol{J}_{\theta}$

- Previous ADP techniques used  $J_{\theta} = \Psi \theta$
- Intuition: take  $J_{\theta} = -\log(\Psi\theta)$  so  $e^{-LJ_{\theta}}$  is linear in  $\theta$
- Surrogate optimization:

$$\min_{\theta} \boldsymbol{c}^{\top} \boldsymbol{J}_{\theta} + \underbrace{\|\boldsymbol{L} \boldsymbol{J}_{\theta} - \boldsymbol{J}_{\theta}\|}_{\text{Bellman error}}$$

(1)

э.

•  $\|\boldsymbol{L}\boldsymbol{J}_{\theta} - \boldsymbol{J}_{\theta}\|$  not convex in  $\theta$ , but

$$e^{-\max\{\boldsymbol{L}\boldsymbol{J}_{ heta}, \boldsymbol{J}_{ heta}\}} \|\boldsymbol{L}\boldsymbol{J}_{ heta} - \boldsymbol{J}_{ heta}\| \leq \left\| e^{-\boldsymbol{L}\boldsymbol{J}_{ heta}} - e^{-\boldsymbol{J}_{ heta}} \right\|$$

• Plugging  $\Psi \theta = e^{-J\theta}$  into (1):

$$\min_{\theta} - \boldsymbol{c}^{\top} \log(\Psi \theta) + || \, \boldsymbol{e}^{-q} \boldsymbol{P}_0 \Psi \theta \, - \Psi \theta ||$$

## Parameterizing $J_{\theta}$

- Previous ADP techniques used  $J_{\theta} = \Psi \theta$
- Intuition: take  $J_{\theta} = -\log(\Psi\theta)$  so  $e^{-LJ_{\theta}}$  is linear in  $\theta$
- Surrogate optimization:

$$\min_{\theta} \boldsymbol{c}^{\top} \boldsymbol{J}_{\theta} + \underbrace{\|\boldsymbol{L} \boldsymbol{J}_{\theta} - \boldsymbol{J}_{\theta}\|}_{\text{Bellman error}}$$

(1)

э.

•  $\|\boldsymbol{L}\boldsymbol{J}_{\theta} - \boldsymbol{J}_{\theta}\|$  not convex in  $\theta$ , but

$$e^{-\max\{\boldsymbol{L}\boldsymbol{J}_{ heta}, \boldsymbol{J}_{ heta}\}} \|\boldsymbol{L}\boldsymbol{J}_{ heta} - \boldsymbol{J}_{ heta}\| \leq \left\| e^{-\boldsymbol{L}\boldsymbol{J}_{ heta}} - e^{-\boldsymbol{J}_{ heta}} \right\|$$

• Plugging  $\Psi \theta = e^{-J\theta}$  into (1):

$$\min_{\theta} - c^{\top} \log(\Psi\theta) + ||\underbrace{e^{-q} P_0 \Psi\theta}_{\text{Bellman}} - \Psi\theta||$$

## Our algorithm

Recall relaxed optimization:

$$\min_{\theta} - \boldsymbol{c}^{\top} \log(\Psi\theta) + \left\| \boldsymbol{e}^{-\boldsymbol{q}} \boldsymbol{P}_{0} \Psi\theta - \Psi\theta \right\|_{\boldsymbol{Q}}$$

Let *T* be the set of trajectories with *x*<sub>1</sub> ~ *c* with distribution *Q*(·)
Optimization is equal to:

$$\min_{\theta} - c^{\top} \log(\Psi \theta) + \sum_{\boldsymbol{T} \in \mathcal{T}} Q(\boldsymbol{T}) \sum_{\boldsymbol{x} \in \mathcal{T}} \left| e^{-q(\boldsymbol{x})} P_0 \Psi \theta(\boldsymbol{x}) - \Psi \theta(\boldsymbol{x}) \right|$$

Use stochastic gradient descent by sampling trajectories

く 同 ト く ヨ ト く ヨ ト -

#### Theorem

Let  $\hat{\theta}$  be an  $\epsilon$ -optimal solution returned by SGD. Then,

$$J_{P_{J_{\widehat{\theta}}}}(\mathbf{x}_{1}) \leq \inf_{\theta \in \Theta} \left\{ J_{P_{J_{\theta}}}(\mathbf{x}_{1}) + \mathcal{E}(J_{\theta}) \right\} + \epsilon \\ + \underbrace{\left\| P_{J_{\widehat{\theta}}} - Q \right\|_{1}}_{Off-policy\ error} \max \sum_{\mathbf{x} \in T} \left| J_{\widehat{\theta}}(\mathbf{x}) - L J_{\widehat{\theta}}(\mathbf{x}) \right|$$

Penalty function:

$$\mathcal{E}(\boldsymbol{J}_{\theta}) = \sum_{\boldsymbol{T} \in \mathcal{T}} \sum_{\boldsymbol{x} \in \boldsymbol{T}} \left( \boldsymbol{Q}(\boldsymbol{T}) \boldsymbol{e}^{-\min(\boldsymbol{J}_{\theta}, \boldsymbol{L} \boldsymbol{J}_{\theta})} + \boldsymbol{P}_{\boldsymbol{J}_{\theta}}(\boldsymbol{T}) \right) \underbrace{|\boldsymbol{J}_{\theta}(\boldsymbol{x}) - \boldsymbol{L} \boldsymbol{J}_{\theta}(\boldsymbol{x})|}_{\text{Small if } \boldsymbol{J}_{\theta} \text{ is }}$$

close to the optimal value

# Crowdsourcing

- Need to label A items.
- Each item has soft label  $\mu_i \in [0, 1]$
- Guess if  $\mu_i \geq \frac{1}{2}$  for as many *i* as we can
- For *t* = 1, ..., *T*:
  - ▶ Pick *i* ∈ {1,..., *A*}
  - Receive  $X_t \sim \text{Bern}(\mu_i)$
- Use Beta prior  $\Rightarrow$  MDP dynamics equivalent to Bayesian updates
- P<sub>0</sub> limits transitions
- $q(\mathbf{x})$  rewards correct labels

P

- Average error of three policies
- Our method requires 10% fewer samples for same accuracy
- Portion of budget vs. soft label
- Harder soft labels receive more budget

Image: A matrix

• Larger difference as *B* grows

18/2

# Conclusion

- Novel framework for low dimensional policies for linearly solvable MDPs
- Algorithm for policy optimization with complexity that scales with dimension of subspace
- First theoretical bounds for approximate linearly solvable MDP solutions
- Demonstrate on pratical example

₹ 9 Q (P

### Proof outline of main theorem

• 
$$\left| J_{P_{J_{\theta^*}}}(\mathbf{X}_1) - J_{\theta^*}(\mathbf{X}_1) \right| = O(\| L J_{\theta^*} - J_{\theta^*} \|)$$

- Similarly bounding  $\left| J_{P_{J\widehat{\theta}}}(\mathbf{x}_{1}) J_{\widehat{\theta}}(\mathbf{x}_{1}) \right| = O\left( \left\| \mathbf{L}J_{\widehat{\theta}} J_{\widehat{\theta}} \right\| \right)$
- $J_{\theta^*}$  and  $J_{\widehat{\theta}}$  are close by the optimization
